```

Summary

proteusPy is a Python package specializing in the modeling and analysis of proteins of known structure with an emphasis on Disulfide Bonds. This package reprises my molecular modeling program *proteus*, @Pabo_1986, and utilizes a new implementation of the Turtle3D class for disulfide and protein modeling. The Disulfide class implements methods to analyze the protein structure stabilizing element known as a *Disulfide Bond*.

The work has resulted in a freely-accessible database of over 120,000 disulfide bonds contained within 35,818 proteins in the RCSB protein databank.

PDB IDs present:	35818
Disulfides loaded:	120494
Average structure resolution:	2.34 Å
Lowest Energy Disulfide:	2q7q_75D_140D
Highest Energy Disulfide:	1toz_456A_467A
Ca distance cutoff:	8.00 Å
Total RAM Used:	31.05 GB.

Motivation

My primary motivation for implementing **proteusPy** was to revisit the RCSB Protein Databank and do a structural analysis of the disulfide bonds con-

tained therein. This necessitated the creation an object-oriented database capable of introspection, analysis and display. The API is available online at: <https://suchanek.github.io/proteusPy/proteusPy.html> and provides more details and numerous examples. # Requirements 1. PC running MacOS, Linux, Windows 2. 16 GB RAM 3. 2 GB disk space

Installation

1. **Install Anaconda:** <http://anaconda.org>
2. **Build the environment.** It's simplest to clone the repo via github since it contains all of the notebooks, test programs and raw Disulfide databases.
 - Install git-lfs
 - <https://help.github.com/en/github/managing-large-files/installing-git-large-file-storage>
 - From a shell prompt:

```
$ git-lfs track "*.csv" "*.pkl" "*.mp4"      $ git clone
https://github.com/suchanek/proteusPy/proteusPy.git  $ cd
proteusPy      $ conda env create --name proteusPy --file=proteusPy.yml
$ conda activate proteusPy      $ pip install .      $ jupyter
nbextension enable --py --sys-prefix widgetsnbextension
$ python -m ipykernel install --user --name proteusPy --display-name
"Python (proteusPy)"
```

General Usage

Once the package is installed one can use the existing notebooks for analysis of the RCSB Disulfide database. The notebooks directory contains all of my Jupyter notebooks and is a good place to start. The DisulfideAnalysis.ipynb notebook contains the first analysis paper. The programs subdirectory contains the primary programs for downloading the RCSB disulfide-containing structure files, DisulfideDownloader.py, extracting the disulfides and creating the database loaders DisulfideExtractor.py and cluster analysis DisulfideClass_Analysis.py.

The first time one loads the database via Load_PDB_SS() the system will attempt to download the full and subset database from my Google Drive. If this fails the system will attempt to rebuild the database from the repo's data subdirectory (not the package's). If you've downloaded from github this will work correctly. If you've installed from pyPi via pip it will fail.

Class Details

The primary classes developed for `proteusPy` are described briefly below. Please see the API for details.

Disulfide

This class provides a Python object and methods representing a physical disulfide bond either extracted from the RCSB protein databank or a virtual one built using the Turtle3D class. The disulfide bond is an important intramolecular stabilizing structural element and is characterized by:

- Atomic coordinates for the atoms $N, C_\alpha, C_\beta, C', S_\gamma$ for both residues. These are stored as both raw atomic coordinates as read from the RCSB file and internal local coordinates.
- The dihedral angles $\chi_1 - \chi_5$ for the disulfide bond
- A name, by default: `{pdb_id}-{prox_resnum}-{prox_chain}-{distal_resnum}-{distal_chain}`
- Proximal residue number
- Distal residue number
- Approximate bond torsional energy (kcal/mol):

$$E_{kcal/mol} \approx 2.0 * \cos(3.0 * \chi_1) + \cos(3.0 * \chi_5) + \cos(3.0 * \chi_2) + \cos(3.0 * \chi_4) + 3.5 * \cos(2.0 * \chi_3) + 0.6 * \cos(3.0 * \chi_3) + 10.1$$

- Euclidean length of the dihedral angles (degrees) defined as:

$$\sqrt{(\chi_1^2 + \chi_2^2 + \chi_3^2 + \chi_4^2 + \chi_5^2)}$$

- $C_\alpha - C_\alpha$ distance (Å)
- $C_\beta - C_\beta$ distance (Å)
- The previous C' and next N coordinates for both the proximal and distal residues. These are needed to calculate the backbone dihedral angles ϕ, ψ .
- Backbone dihedral angles ϕ and ψ , when possible. Not all structures are complete and in those cases the atoms needed may be undefined. In this case the ϕ and ψ angles are set to -180°.

The class also provides 3D rendering capabilities using the excellent PyVista library, and can display disulfides interactively in a variety of display styles: * 'sb' - Split Bonds style - bonds colored by their atom type * 'bs' - Ball and Stick style - split bond coloring with small atoms * 'pd' - Proximal/Distal style - bonds colored *Red* for proximal residue and *Green* for the distal residue. * 'cpk' - CPK style rendering, colored by atom type: * Carbon - Grey * Nitrogen - Blue * Sulfur - Yellow * Oxygen - Red * Hydrogen - White

Individual renderings can be saved to a file and animations can be created. The *cpk* and *bs* styles are illustrated below:

DisulfideLoader

This class represents the disulfide database itself and is its primary means of accession. Instantiation takes 2 parameters: **subset** and **verbose**. Given the size of the database, one can use the **subset** parameter to load the first 1000 disulfides into memory. This facilitates quicker development and testing new functions. I recommend using at least a 16 GB machine to work with the full dataset.

The entirety of the RCSB disulfide database is stored within the class via a `DisulfideList`, a `Pandas` .csv file, and a dict of indices mapping the RCSB IDs into their respective list of disulfides. The datastructures allow simple, direct and flexible access to the disulfide structures contained within. This makes it possible to access the disulfides by array index, RCSB structure ID or disulfide name.

Example:

```
>>> import proteusPy
>>> from proteusPy.Disulfide import Disulfide
>>> from proteusPy.DisulfideLoader import DisulfideLoader
>>> from proteusPy.DisulfideList import DisulfideList
>>> SS1 = DisulfideList([], 'tmp1')
>>> SS2 = DisulfideList([], 'tmp2')
```

```
>>> PDB_SS = DisulfideLoader(verbose=False, subset=True)
```

Accessing by index value:

```
>>> SS1 = PDB_SS[0]
```

```
>>> SS1
```

```
<Disulfide 4yys_22A_65A, Source: 4yys, Resolution: 1.35 Å>
```

Accessing by PDB_ID returns a list of Disulfides:

```
>>> SS2 = PDB_SS['4yys']
```

```
>>> SS2
```

```
[<Disulfide 4yys_22A_65A, Source: 4yys, Resolution: 1.35 Å>, <Disulfide 4yys_56A_98A, Source: 4yys, Resolution: 1.35 Å>]
```

Accessing individual disulfides by their name:

```
>>> SS3 = PDB_SS['4yys_56A_98A']
```

```
>>> SS3
```

```
<Disulfide 4yys_56A_98A, Source: 4yys, Resolution: 1.35 Å>
```

Finally, we can access disulfides by regular slicing:

```
>>> SSlist = PDB_SS[:4]
```

The class can also render Disulfides overlaid on a common coordinate system to a pyVista window using the `DisulfideLoader.display__overlay()` method.

NB: For typical usage one accesses the database via the `Load_PDB_SS()` function. This function loads the compressed database from its single source. Initializing a `DisulfideLoader()` object will load the individual torsions and disulfide .pkl files, builds the classlist structures, and writes the completely built object to a single .pkl file. This requires the raw .pkl files created by download process. These files are contained in the repository `data` directory.

turtle3D

The `turtle3D` is an object that maintains a *local coordinate system* in three dimensional space. This coordinate system consists of: * a Position vector * a Heading vector * a Left vector * an Up vector

These vectors fully define the object's position and orientation in a *local* coordinate frame. The `to__local` and `to__global` methods convert between these two. These methods make it possible to readily compare different disulfides by:

1. Orienting the turtle at the disulfide's proximal residue in a standard orientation.
2. Converting the global coordinates of the disulfide as read from the RCSB into local coordinates.
3. Saving all of the local coordinates with the raw coordinates
4. Performing RMS distance and angle calculations

The turtle has several molecule-specific functions including `orient__at__residue` and `orient__from__backbone`.

By implementing the functions `Move`, `Roll`, `Yaw`, `Pitch` and `Turn` the turtle is capable of movement in a three-dimensional space. See [Pabo_1986] for more details.

Database Creation

The following steps were performed to create the RCSB database: 1. Identify disulfide containing proteins in the RCSB. I generated a query using the web-based query tool for all proteins containing one or more disulfide bond. The resulting file consisted of 35819 IDs. 2. Download the structure files to disk. This resulted in the program `DisulfideDownloader.py`. The download took approximately twelve hours. 3. Extract the disulfides from the downloaded structures. The program `DisulfideExtractor.py` was used to extract disulfides from the individual structure files. This seemingly simple task was complicated by several factors including: 1. Duplicate disulfides contained within a multi-chain protein file. 2. Physically impossible disulfides, where the $C_\alpha - C_\alpha$ distance is $> 8\text{\AA}$. 3. Structures with disordered CYS atoms.

In the end I elected to only use a single example of a given disulfide from a multi-chain entry, and removed any disulfides with a $C_\alpha - C_\alpha$ distance is $> 8\text{\AA}$. This resulted in the current database consisting of 35,808 structures and 120,494 disulfide bonds. To my knowledge this is the only searchable database of disulfide bonds in existence.

The Future

I am continuing to explore binary and disulfide structural classes using the sextant class approach. This offers much higher class resolution and reveals subgroups within the broad class. Than the binary approach described by Hogg et al. I'd also like to explore the catalytic and allosteric classes in more detail to look for common structural elements.

I also intend to deploy a Disulfide Database browser for exploration and analysis. This is ongoing.

Misc

Developer's Notes: The .pkl files needed to instantiate this class and save it into its final .pkl file are defined in the proteusPy.data class and should not be changed. Upon initialization the class will load them and initialize itself.

NB: proteusPy relies on my fork of the Biopython Python package to download and build the database, (<https://github.com/suchanek/biopython>). As a result, one can't download and create the database locally unless the BioPython patch is applied. The changed python file is in the repo's data directory - `parse_pdb_header.py`. Database analysis is unaffected without the patch. Also, if you're running on an M-series Mac then it's important to install Biopython first, since the generic release won't build on the M1. 7/4/23 -egs-
